Lecture 2: Markov Decision Processes

#### Lecture 2: Markov Decision Processes

David Silver

#### 1 Markov Processes

Almost all RL problems can be formalized as MDPs

A Markov Process (or Markov Chain ) is a tuple  $\langle$  S, P  $\rangle$ 

#### 2 Markov Reward Processes

A Markov reward process is a Markov chain with values.

A Markov Reward Process is a tuple (S, P, R, γ)

Bellman Equation and Matrix

#### 3 Markov Decision Processes

A Markov decision process ( MDP ) is a Markov reward process with decisions.

4 Extensions to MDPs

A Markov Decision Process is a tuple 〈 S, A, P, R, γ〉

Policy

Value function: state-value func, action-value func

Bellman Expectation Equation and Matrix

Optimal value func/ Policy

Bellman Optimality Equation and Solving

Value/Policy iteration

Q-learning

Sarsa

#### Introduction to MDPs

- Markov decision processes formally describe an environment for reinforcement learning
- Where the environment is *fully observable*
- i.e. The current *state* completely characterises the process
- Almost all RL problems can be formalised as MDPs, e.g.
  - Optimal control primarily deals with continuous MDPs
  - Partially observable problems can be converted into MDPs
  - Bandits are MDPs with one state

### Markov Property

"The future is independent of the past given the present"

#### Definition

A state  $S_t$  is *Markov* if and only if

$$\mathbb{P}[S_{t+1} \mid S_t] = \mathbb{P}[S_{t+1} \mid S_1, ..., S_t]$$

- The state captures all relevant information from the history
- Once the state is known, the history may be thrown away
- i.e. The state is a sufficient statistic of the future

#### State Transition Matrix

For a Markov state s and successor state s', the state transition probability is defined by

$$\mathcal{P}_{ss'} = \mathbb{P}\left[S_{t+1} = s' \mid S_t = s\right]$$

State transition matrix  $\mathcal{P}$  defines transition probabilities from all states s to all successor states s',

$$\mathcal{P} = from \begin{bmatrix} \mathcal{P}_{11} & \dots & \mathcal{P}_{1n} \\ \vdots & & & \\ \mathcal{P}_{n1} & \dots & \mathcal{P}_{nn} \end{bmatrix}$$

where each row of the matrix sums to 1.

# Markov Process

A Markov process is a memoryless random process, i.e. a sequence of random states  $S_1, S_2, ...$  with the Markov property.

#### Definition

- A Markov Process (or Markov Chain) is a tuple (S, P)
  - lacksquare  $\mathcal{S}$  is a (finite) set of states
  - $\mathcal{P}$  is a state transition probability matrix,  $\mathcal{P}_{ss'} = \mathbb{P}\left[S_{t+1} = s' \mid S_t = s\right]$

### Example: Student Markov Chain

### Example: Student Markov Chain Episodes

Sample episodes for Student Markov Chain starting from  $S_1 = C1$ 

$$S_1, S_2, ..., S_T$$

- C1 C2 C3 Pub C2 C3 Pass Sleep
- C1 FB FB C1 C2 C3 Pub C1 FB FB FB C1 C2 C3 Pub C2 Sleep

#### Example: Student Markov Chain Transition Matrix

#### Markov Reward Process

A Markov reward process is a Markov chain with values.

#### Definition

#### A Markov Reward Process is a tuple $\langle \mathcal{S}, \mathcal{P}, \mathcal{R}, \gamma \rangle$

- lacksquare  $\mathcal{S}$  is a finite set of states
- $\mathcal{P}$  is a state transition probability matrix,

$$\mathcal{P}_{ss'} = \mathbb{P}\left[S_{t+1} = s' \mid S_t = s\right]$$

- $\mathcal{R}$  is a reward function,  $\mathcal{R}_s = \mathbb{E}\left[R_{t+1} \mid S_t = s\right]$
- lacksquare  $\gamma$  is a discount factor,  $\gamma \in [0,1]$

### Example: Student MRP

#### Return

Return

#### Definition

The return  $G_t$  is the total discounted reward from time-step t.

$$G_t = R_{t+1} + \gamma R_{t+2} + \dots = \sum_{k=0}^{\infty} \gamma^k R_{t+k+1}$$

- The discount  $\gamma \in [0,1]$  is the present value of future rewards
- The value of receiving reward R after k+1 time-steps is  $\gamma^k R$ .
- This values immediate reward above delayed reward.
  - $lue{\gamma}$  close to 0 leads to "myopic" evaluation
  - ullet  $\gamma$  close to 1 leads to "far-sighted" evaluation

### Why discount?

Most Markov reward and decision processes are discounted. Why?

- Mathematically convenient to discount rewards
- Avoids infinite returns in cyclic Markov processes
- Uncertainty about the future may not be fully represented
- If the reward is financial, immediate rewards may earn more interest than delayed rewards
- Animal/human behaviour shows preference for immediate reward
- It is sometimes possible to use *undiscounted* Markov reward processes (i.e.  $\gamma=1$ ), e.g. if all sequences terminate.

#### Value Function

The value function v(s) gives the long-term value of state s

#### Definition

The state value function v(s) of an MRP is the expected return starting from state s

$$v(s) = \mathbb{E}\left[G_t \mid S_t = s\right]$$

discounted rewards

#### Example: Student MRP Returns

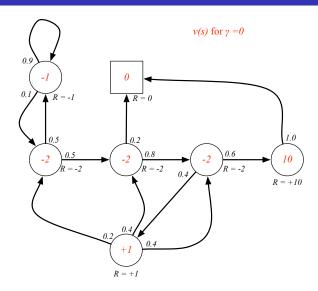

Sample returns for Student MRP: Starting from  $S_1 = C1$  with  $\gamma = \frac{1}{2}$ 

$$G_1 = R_2 + \gamma R_3 + \dots + \gamma^{T-2} R_T$$

```

└─Value Function

# Example: State-Value Function for Student MRP (2)

└─Value Function

# Example: State-Value Function for Student MRP (3)

### Bellman Equation for MRPs

The value function can be decomposed into two parts:

- $\blacksquare$  immediate reward  $R_{t+1}$
- discounted value of successor state  $\gamma v(S_{t+1})$

$$v(s) = \mathbb{E} [G_t \mid S_t = s]$$

$$= \mathbb{E} [R_{t+1} + \gamma R_{t+2} + \gamma^2 R_{t+3} + \dots \mid S_t = s]$$

$$= \mathbb{E} [R_{t+1} + \gamma (R_{t+2} + \gamma R_{t+3} + \dots) \mid S_t = s]$$

$$= \mathbb{E} [R_{t+1} + \gamma G_{t+1} \mid S_t = s]$$

$$= \mathbb{E} [R_{t+1} + \gamma v(S_{t+1}) \mid S_t = s]$$

# Bellman Equation for MRPs (2)

$$v(s) = \mathbb{E}\left[R_{t+1} + \gamma v(S_{t+1}) \mid S_t = s\right]$$

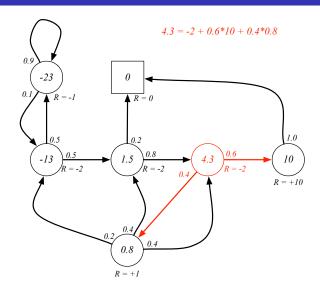

$$v(s) \leftarrow s$$

$$r$$

$$v(s') \leftarrow s'$$

$$v(s) = \mathcal{R}_s + \gamma \sum_{s' \in \mathcal{S}} \mathcal{P}_{ss'} v(s')$$

### Example: Bellman Equation for Student MRP

### Bellman Equation in Matrix Form

The Bellman equation can be expressed concisely using matrices,

$$\mathbf{v} = \mathcal{R} + \gamma \mathcal{P} \mathbf{v}$$

where v is a column vector with one entry per state

$$\begin{bmatrix} v(1) \\ \vdots \\ v(n) \end{bmatrix} = \begin{bmatrix} \mathcal{R}_1 \\ \vdots \\ \mathcal{R}_n \end{bmatrix} + \gamma \begin{bmatrix} \mathcal{P}_{11} & \dots & \mathcal{P}_{1n} \\ \vdots & & \\ \mathcal{P}_{n1} & \dots & \mathcal{P}_{nn} \end{bmatrix} \begin{bmatrix} v(1) \\ \vdots \\ v(n) \end{bmatrix}$$

### Solving the Bellman Equation

- The Bellman equation is a linear equation
- It can be solved directly:

$$v = \mathcal{R} + \gamma \mathcal{P} v$$
$$(I - \gamma \mathcal{P}) v = \mathcal{R}$$
$$v = (I - \gamma \mathcal{P})^{-1} \mathcal{R}$$

- Computational complexity is  $O(n^3)$  for n states
- Direct solution only possible for small MRPs
- There are many iterative methods for large MRPs, e.g.
  - Dynamic programming
  - Monte-Carlo evaluation
  - Temporal-Difference learning

#### Markov Decision Process

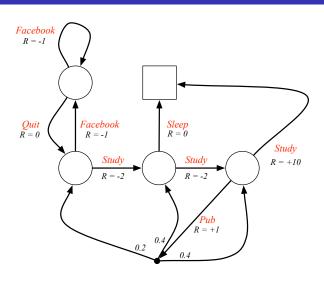

A Markov decision process (MDP) is a Markov reward process with decisions. It is an *environment* in which all states are Markov.

#### Definition

#### A Markov Decision Process is a tuple $\langle S, A, P, R, \gamma \rangle$

- lacksquare  $\mathcal S$  is a finite set of states
- $\blacksquare$   $\mathcal{A}$  is a finite set of actions
- $\mathcal{P}$  is a state transition probability matrix,  $\mathcal{P}_{sc'}^{a} = \mathbb{P}\left[S_{t+1} = s' \mid S_t = s, A_t = a\right]$
- $\mathcal{R}$  is a reward function,  $\mathcal{R}_s^a = \mathbb{E}\left[R_{t+1} \mid S_t = s, A_t = a\right]$
- $\gamma$  is a discount factor  $\gamma \in [0, 1]$ .

### Example: Student MDP

# Policies (1)

#### Definition

A policy  $\pi$  is a distribution over actions given states,

$$\pi(a|s) = \mathbb{P}\left[A_t = a \mid S_t = s\right]$$

- A policy fully defines the behaviour of an agent
- MDP policies depend on the current state (not the history)
- i.e. Policies are *stationary* (time-independent),  $A_t \sim \pi(\cdot|S_t), \forall t > 0$

└ Policies

# Policies (2)

- Given an MDP  $\mathcal{M} = \langle \mathcal{S}, \mathcal{A}, \mathcal{P}, \mathcal{R}, \gamma \rangle$  and a policy  $\pi$
- The state sequence  $S_1, S_2, ...$  is a Markov process  $\langle \mathcal{S}, \mathcal{P}^\pi \rangle$
- The state and reward sequence  $S_1, R_2, S_2, ...$  is a Markov reward process  $\langle S, \mathcal{P}^{\pi}, \mathcal{R}^{\pi}, \gamma \rangle$
- where

$$\mathcal{P}^{\pi}_{s,s'} = \sum_{a \in \mathcal{A}} \pi(a|s) \mathcal{P}^{a}_{ss'}$$
 $\mathcal{R}^{\pi}_{s} = \sum_{a \in \mathcal{A}} \pi(a|s) \mathcal{R}^{a}_{s}$ 

└─Value Functions

#### Value Function

#### Definition

The state-value function  $v_{\pi}(s)$  of an MDP is the expected return starting from state s, and then following policy  $\pi$ 

$$v_{\pi}(s) = \mathbb{E}_{\pi}\left[G_t \mid S_t = s\right]$$

#### Definition

The action-value function  $q_{\pi}(s,a)$  is the expected return starting from state s, taking action a, and then following policy  $\pi$ 

$$q_{\pi}(s,a) = \mathbb{E}_{\pi}\left[G_t \mid S_t = s, A_t = a\right]$$

#### Example: State-Value Function for Student MDP

The state-value function can again be decomposed into immediate reward plus discounted value of successor state,

$$v_{\pi}(s) = \mathbb{E}_{\pi} \left[ R_{t+1} + \gamma v_{\pi}(S_{t+1}) \mid S_t = s \right]$$

The action-value function can similarly be decomposed,

$$q_{\pi}(s, a) = \mathbb{E}_{\pi} \left[ R_{t+1} + \gamma q_{\pi}(S_{t+1}, A_{t+1}) \mid S_t = s, A_t = a \right]$$

### Bellman Expectation Equation for $V^\pi$

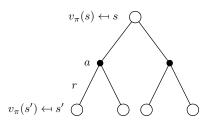

$$v_\pi(s) = \sum_{\mathsf{a} \in \mathcal{A}} \pi(\mathsf{a}|s) q_\pi(s,\mathsf{a})$$

# Bellman Expectation Equation for $Q^{\pi}$

$$q_{\pi}(s, a) = \mathcal{R}_{s}^{a} + \gamma \sum_{s' \in \mathcal{S}} \mathcal{P}_{ss'}^{a} v_{\pi}(s')$$

# Bellman Expectation Equation for $v_{\pi}$ (2)

$$v_{\pi}(s) = \sum_{a \in \mathcal{A}} \pi(a|s) \left(\mathcal{R}_{s}^{a} + \gamma \sum_{s' \in \mathcal{S}} \mathcal{P}_{ss'}^{a} v_{\pi}(s')\right)$$

# Bellman Expectation Equation for $q_{\pi}$ (2)

$$q_{\pi}(s,a) \longleftrightarrow s,a$$

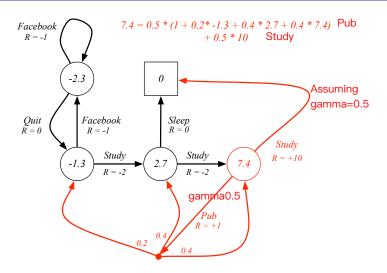

$$r$$

$$s'$$

$$q_{\pi}(s',a') \longleftrightarrow a'$$

$$q_{\pi}(s, a) = \mathcal{R}_{s}^{a} + \gamma \sum_{s' \in \mathcal{S}} \mathcal{P}_{ss'}^{a} \sum_{a' \in \mathcal{A}} \pi(a'|s') q_{\pi}(s', a')$$

### Example: Bellman Expectation Equation in Student MDP

# Bellman Expectation Equation (Matrix Form)

The Bellman expectation equation can be expressed concisely using the induced MRP,

$$\mathbf{v}_{\pi} = \mathcal{R}^{\pi} + \gamma \mathcal{P}^{\pi} \mathbf{v}_{\pi}$$

with direct solution

$$v_{\pi} = (I - \gamma \mathcal{P}^{\pi})^{-1} \mathcal{R}^{\pi}$$

## Optimal Value Function

#### Definition

The optimal state-value function  $v_*(s)$  is the maximum value function over all policies

The optimal action-value function  $q_*(s,a)$  is the maximum action-value function over all policies

best among them. q\_\* is the possible max reward you can get after  $q_*(s,a) = \max_{\pi} q_{\pi}(s,a)$  action a at state s.

We want to know q \*.

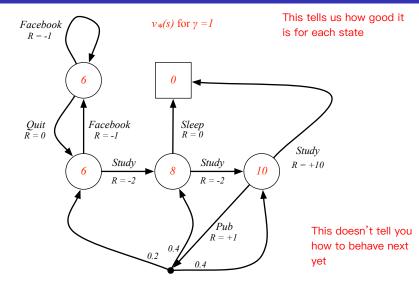

You have multiple ways to

traverse the system (multiple

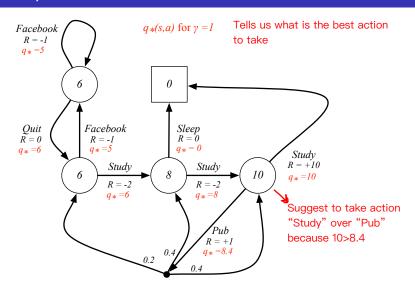

■ The optimal value function specifies the best possible performance in the MDP.

■ An MDP is "solved" when we know the optimal value fn. solve q\_\*

## Example: Optimal Value Function for Student MDP

# Example: Optimal Action-Value Function for Student MDP

# Optimal Policy What is the best way to behave in MDP

Define a partial ordering over policies

$$\pi \geq \pi'$$
 if  $v_{\pi}(s) \geq v_{\pi'}(s), orall s$ 

Define which policy (pi) is better. It cannot be worse. It must be better/equal in all states.

#### Theorem

For any Markov Decision Process

- There exists an optimal policy  $\pi_*$  that is better than or equal to all other policies,  $\pi_* \geq \pi, \forall \pi$
- All optimal policies achieve the optimal value function,  $v_{\pi_*}(s) = v_*(s)$
- All optimal policies achieve the optimal action-value function,  $q_{\pi_*}(s,a) = q_*(s,a)$

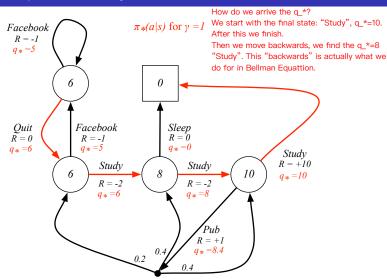

# Finding an Optimal Policy

An optimal policy can be found by maximising over  $q_*(s, a)$ ,

$$\pi_*(a|s) = \left\{ egin{array}{ll} 1 & ext{if } a = ext{argmax } q_*(s,a) \ & a \in \mathcal{A} \ 0 & otherwise \end{array} 
ight.$$

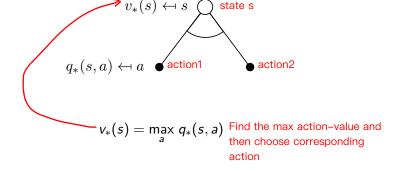

- There is always a deterministic optimal policy for any MDP
- If we know  $q_*(s, a)$ , we immediately have the optimal policy

## Example: Optimal Policy for Student MDP

## Bellman Optimality Equation for $v_*$ Tells us how to solve a MDP

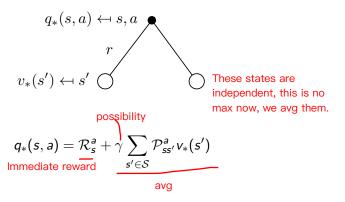

The optimal value functions are recursively related by the Bellman optimality equations:

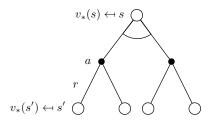

# Bellman Optimality Equation for 💸

# Bellman Optimality Equation for $V^*$ (2)

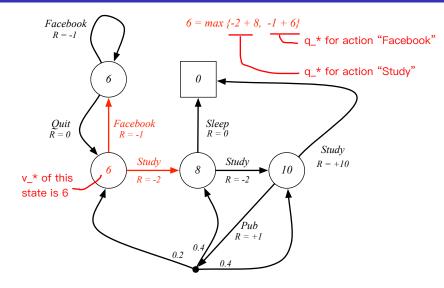

Recursion relationship between v\_\* to itself. So  $v_*(s) = \max_{s} \mathcal{R}_s^s + \gamma \sum_{s' \in \mathcal{S}} \mathcal{P}_{ss'}^s v_*(s')$  this equation can be solved.

# Bellman Optimality Equation for $Q^*$ (2)

$$q_*(s, a) = \mathcal{R}_s^a + \gamma \sum_{s' \in \mathcal{S}} \mathcal{P}_{ss'}^a \max_{a'} q_*(s', a')$$

# Example: Bellman Optimality Equation in Student MDP

# Solving the Bellman Optimality Equation

- Bellman Optimality Equation is non-linear
- No closed form solution (in general)
- Many iterative solution methods
  - Value Iteration
  - Policy Iteration
  - Q-learning
  - Sarsa

### Extensions to MDPs

(no exam)

- Infinite and continuous MDPs
- Partially observable MDPs
- Undiscounted, average reward MDPs

### Infinite MDPs

(no exam)

The following extensions are all possible:

- Countably infinite state and/or action spaces
  - Straightforward
- Continuous state and/or action spaces
  - Closed form for linear quadratic model (LQR)
- Continuous time
  - Requires partial differential equations
  - Hamilton-Jacobi-Bellman (HJB) equation
  - $\blacksquare$  Limiting case of Bellman equation as time-step  $\to 0$

## **POMDPs**

(no exam)

A Partially Observable Markov Decision Process is an MDP with hidden states. It is a hidden Markov model with actions.

### Definition

A *POMDP* is a tuple  $\langle \mathcal{S}, \mathcal{A}, \mathcal{O}, \mathcal{P}, \mathcal{R}, \mathcal{Z}, \gamma \rangle$ 

- lacksquare  $\mathcal S$  is a finite set of states
- lacksquare  $\mathcal{A}$  is a finite set of actions
- O is a finite set of observations
- $m{\mathcal{P}}$  is a state transition probability matrix,

$$\mathcal{P}_{ss'}^{a} = \mathbb{P}\left[S_{t+1} = s' \mid S_t = s, A_t = a\right]$$

- lacksquare  $\mathcal{R}$  is a reward function,  $\mathcal{R}_s^a = \mathbb{E}\left[R_{t+1} \mid S_t = s, A_t = a\right]$
- **Z** is an observation function,  $\mathcal{Z}_{c',a}^{a} = \mathbb{P}\left[O_{t+1} = o \mid S_{t+1} = s', A_t = a\right]$
- $\bullet$   $\gamma$  is a discount factor  $\gamma \in [0, 1]$ .

### **Belief States**

(no exam)

#### Definition

A *history*  $H_t$  is a sequence of actions, observations and rewards,

$$H_t = A_0, O_1, R_1, ..., A_{t-1}, O_t, R_t$$

### Definition

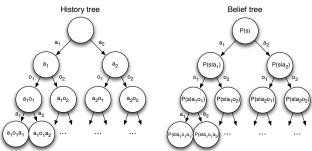

A belief state b(h) is a probability distribution over states, conditioned on the history h

$$b(h) = (\mathbb{P}[S_t = s^1 \mid H_t = h], ..., \mathbb{P}[S_t = s^n \mid H_t = h])$$

### Reductions of POMDPs

(no exam)

- The history  $H_t$  satisfies the Markov property
- The belief state  $b(H_t)$  satisfies the Markov property

- A POMDP can be reduced to an (infinite) history tree
- A POMDP can be reduced to an (infinite) belief state tree

## Ergodic Markov Process

(no exam)

An ergodic Markov process is

- Recurrent: each state is visited an infinite number of times
- Aperiodic: each state is visited without any systematic period

#### **Theorem**

An ergodic Markov process has a limiting stationary distribution  $d^{\pi}(s)$  with the property

$$d^{\pi}(s) = \sum_{s' \in \mathcal{S}} d^{\pi}(s') \mathcal{P}_{s's}$$

### (no exam)

#### Definition

An MDP is ergodic if the Markov chain induced by any policy is ergodic.

For any policy  $\pi$ , an ergodic MDP has an average reward per time-step  $\rho^{\pi}$  that is independent of start state.

$$\rho^{\pi} = \lim_{T \to \infty} \frac{1}{T} \mathbb{E} \left[ \sum_{t=1}^{T} R_t \right]$$

- The value function of an undiscounted, ergodic MDP can be expressed in terms of average reward.
- $\tilde{v}_{\pi}(s)$  is the extra reward due to starting from state s,

$$ilde{v}_{\pi}(s) = \mathbb{E}_{\pi}\left[\sum_{k=1}^{\infty}\left(R_{t+k} - 
ho^{\pi}\right) \mid S_{t} = s
ight]$$

There is a corresponding average reward Bellman equation,

$$egin{aligned} ilde{v}_{\pi}(s) &= \mathbb{E}_{\pi} \left[ (R_{t+1} - 
ho^{\pi}) + \sum_{k=1}^{\infty} (R_{t+k+1} - 
ho^{\pi}) \mid S_{t} = s 
ight] \ &= \mathbb{E}_{\pi} \left[ (R_{t+1} - 
ho^{\pi}) + ilde{v}_{\pi}(S_{t+1}) \mid S_{t} = s 
ight] \end{aligned}$$
